Random Intervals  
and Confidence  
Intervals (Ch. 6.1)

Will Landau

Motivation

Random Intervals

Confidence  
Intervals  
( $n \geq 25$ ,  $\sigma$   
known)

Motivation

Random Intervals

Confidence Intervals ( $n \geq 25$ ,  $\sigma$  known)

- ▶ **Statistical inference:** using data from the sample to draw formal conclusions about the population
  - ▶ Point estimation (confidence intervals): estimating population parameters and specifying the degree of precision of the estimate.
  - ▶ Hypothesis testing: testing the validity of statements about the population that are framed in terms of parameters.

# Motivation for confidence intervals

- ▶ We want information on a population. For example:
  - ▶ True mean breaking strength of a kind of wire rope.
  - ▶ True mean fill weight of food jars.
  - ▶ True mean instrumental drift of a kind of scale.
  - ▶ Average number of cycles to failure of a kind of spring.
- ▶ We can use point estimates:
  - ▶ For example: if we measure breaking strengths (in tons) of 6 wire ropes as 5, 3, 7, 3, 10, and 1, we might estimate the true mean breaking strength
$$\mu \approx \bar{x} = \frac{5+3+7+3+10+1}{6} = 4.83 \text{ tons.}$$
- ▶ Or, we can use interval estimates:
  - ▶  $\mu$  is likely to be inside the interval  $(4.83 - 2, 4.83 + 2) = (2.83, 6.83)$ .
  - ▶ We are confident that the true mean breaking strength,  $\mu$ , is somewhere in  $(2.83, 6.83)$ . But how confident can we be?

# Outline

Random Intervals  
and Confidence  
Intervals (Ch. 6.1)

Will Landau

Motivation

Random Intervals

Confidence  
Intervals  
( $n \geq 25$ ,  $\sigma$   
known)

Motivation

Random Intervals

Confidence Intervals ( $n \geq 25$ ,  $\sigma$  known)

- ▶ A **random interval** is an interval on the real line with a random variable at one or both of the endpoints.
- ▶ Examples:
  - ▶  $(Z - 2, Z + 2)$ ,  $Z \sim N(0, 1)$
  - ▶  $(Z, \infty)$
  - ▶  $(-\infty, X)$ ,  $X \sim N(-2, 9)$
  - ▶  $(T - s \cdot t_{7,0.975}, T + s \cdot t_{7,0.975})$ ,  $T \sim t_7$
  - ▶  $(X - \sigma \cdot z_{1-\alpha}, \infty)$ ,  $X \sim N(5, \sigma^2)$ ,  $0 < \alpha < 1$ .
- ▶ Random intervals take into account the uncertainty in the measurement of a true mean,  $\mu$ .

## Example: instrumental drift

- ▶ Let  $Z$  be a measure of instrumental drift of a random voltmeter that comes out of a certain factory. Say  $Z \sim N(0, 1)$ .
- ▶ Define a random interval:

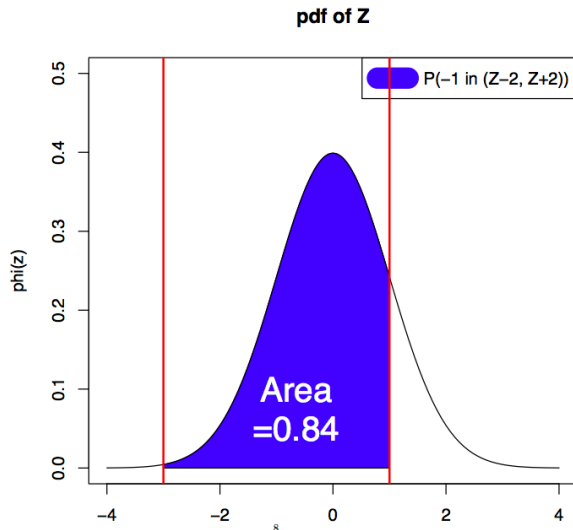

$$(Z - 2, Z + 2)$$

- ▶ What is the probability that  $-1$  is inside the interval?
  - ▶ Equivalent to asking how likely it is that the drift of the next instrument is within 2 units of  $-1$ .

## Example: instrumental drift

$$\begin{aligned}P(-1 \text{ in } (Z - 2, Z + 2)) &= P(Z - 2 < -1 < Z + 2) \\&= P(Z - 1 < 0 < Z + 3) \\&= P(-1 < -Z < 3) \\&= P(-3 < Z < 1) \\&= P(Z \leq 1) - P(Z \leq -3) \\&= \Phi(1) - \Phi(-3) \\&= 0.84\end{aligned}$$

Example: instrumental drift: the range of  $Z$  values for which  $-1$  is in  $(Z - 2, Z + 2)$

# Your turn: random intervals

Calculate:

1.  $P(2 \text{ in } (X - 1, X + 1)), X \sim N(2, 4)$
2.  $P(6.6 \text{ in } (X - 2, X + 1)), X \sim N(7, 2)$

Here,  $0 < \alpha < 1$ .

# Answers: random intervals

1.  $X \sim N(2, 4)$

$$\begin{aligned} P(2 \in (X - 1, X + 1)) &= P(X - 1 < 2 < X + 1) \\ &= P(-1 < 2 - X < 1) \\ &= P(-1 < X - 2 < 1) \\ &= P\left(\frac{-1}{2} < \frac{X - 2}{2} < \frac{1}{2}\right) \\ &= P(-0.5 < Z < 0.5) \\ &= \Phi(0.5) - \Phi(-0.5) \\ &= 0.69 - 0.31 \\ &= 0.38 \end{aligned}$$

2.  $X \sim N(7, 2)$

$$\begin{aligned}P(6.6 \in (X - 2, X + 1)) &= P(X - 2 < 6.6 < X + 1) \\&= P(-2 < 6.6 - X < 1) \\&= P(-1 < X - 6.6 < 2) \\&= P(-1.4 < X - 7 < 1.6) \\&= P\left(\frac{-1.4}{\sqrt{2}} < \frac{X - 7}{\sqrt{2}} < \frac{1.6}{\sqrt{2}}\right) \\&= P(-0.99 < Z < 1.13) \\&= \Phi(1.13) - \Phi(-0.99) \\&= 0.87 - 0.16 \\&= 0.71\end{aligned}$$

# More abstract random intervals

- ▶ Let's say  $X_1, X_2, \dots, X_n$  are iid with:
  - ▶  $n \geq 25$
  - ▶ mean  $\mu$
  - ▶ variance  $\sigma^2$
- ▶ The random interval,  $(\bar{X} - z_{1-\alpha} \frac{\sigma}{\sqrt{n}}, \infty)$ , is useful for estimating  $\mu$  ( $0 < \alpha < 1$ ).
- ▶ The interval contains  $\mu$  with probability  $1 - \alpha$ .

$$\begin{aligned} P(\mu \in (\bar{X} - z_{1-\alpha} \frac{\sigma}{\sqrt{n}}, \infty)) \\ &= P\left(\bar{X} - z_{1-\alpha} \frac{\sigma}{\sqrt{n}} < \mu\right) \\ &= P\left(\bar{X} - \mu < z_{1-\alpha} \frac{\sigma}{\sqrt{n}}\right) \\ &= P\left(\frac{\bar{X} - \mu}{\sigma/\sqrt{n}} < z_{1-\alpha}\right) \\ &\approx P(Z < z_{1-\alpha}) \quad (\text{Central Limit Theorem}) \\ &= \Phi(z_{1-\alpha}) \\ &= 1 - \alpha \quad (\text{by the definition of } z_p) \end{aligned}$$

# Your turn: abstract random intervals

Calculate:

1.  $P(\mu \in (-\infty, \bar{X} + z_{1-\alpha} \frac{\sigma}{\sqrt{n}})), \bar{X} \sim N(\mu, \sigma^2)$
2.  $P(\mu \in (\bar{X} - z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{X} + z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}})), X \sim N(\mu, \sigma^2)$

Remember the Central Limit Theorem:

$$\frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \approx N(0, 1)$$

# Answers: abstract random intervals

1.

$$\begin{aligned} &P\left(\mu \in \left(-\infty, \bar{X} + z_{1-\alpha} \frac{\sigma}{\sqrt{n}}\right)\right) \\ &= P\left(\mu < \bar{X} + z_{1-\alpha} \frac{\sigma}{\sqrt{n}}\right) \\ &= P\left(-z_{1-\alpha} \frac{\sigma}{\sqrt{n}} < \bar{X} - \mu\right) \\ &= P\left(-z_{1-\alpha} < \frac{\bar{X} - \mu}{\sigma/\sqrt{n}}\right) \\ &\approx P(-z_{1-\alpha} < Z) \quad (\text{Central Limit Theorem}) \\ &= 1 - P(Z \leq -z_{1-\alpha}) \\ &= 1 - \Phi(-z_{1-\alpha}) \\ &= 1 - \Phi(z_\alpha) \quad (\text{by symmetry: } N(0,1) \text{ pdf}) \\ &= 1 - \alpha \quad (\text{by the definition of } z_p) \end{aligned}$$

# Answers: abstract random intervals

2.

$$\begin{aligned} &P\left(\mu \in \left(\bar{X} - z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{X} + z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}\right)\right) \\ &= P\left(\bar{X} - z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}} < \mu < \bar{X} + z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}\right) \\ &= P\left(-z_{1-\alpha/2} \cdot \frac{\sigma}{\sqrt{n}} < \mu - \bar{X} < z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}\right) \\ &= P\left(-z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}} < \bar{X} - \mu < z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}\right) \\ &= P\left(-z_{1-\alpha/2} < \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} < z_{1-\alpha/2}\right) \\ &\approx P(-z_{1-\alpha/2} < Z < z_{1-\alpha/2}) \quad (\text{Central Limit Theorem}) \\ &= \Phi(z_{1-\alpha/2}) - \Phi(-z_{1-\alpha/2}) \\ &= \Phi(z_{1-\alpha/2}) - \Phi(z_{\alpha/2}) \quad (\text{by symmetry: } N(0,1) \text{ pdf}) \\ &= \left(1 - \frac{\alpha}{2}\right) - \frac{\alpha}{2} = 1 - \alpha \end{aligned}$$

# Outline

Random Intervals  
and Confidence  
Intervals (Ch. 6.1)

Will Landau

Motivation

Random Intervals

Confidence  
Intervals  
( $n \geq 25$ ,  $\sigma$   
known)

Motivation

Random Intervals

Confidence Intervals ( $n \geq 25$ ,  $\sigma$  known)

- ▶ A  $1 - \alpha$  **confidence interval** for an unknown parameter is the finite realization of a random interval that contains that parameter with probability  $1 - \alpha$ .
- ▶  $1 - \alpha$  is called the **confidence level** of the interval.
- ▶ Example: for observations  $x_1, x_2, \dots, x_n$  from random variables  $X_1, X_2, \dots, X_n$  iid with  $E(X_1) = \mu$ ,  $Var(X_1) = \sigma^2$ , a  $1 - \alpha$  confidence interval for  $\mu$  is:

$$\left( \bar{X} - z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{X} + z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}} \right)$$

which is a random draw from the random interval:

$$\left( \bar{X} - z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{X} + z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}} \right)$$

# Confidence intervals for $\mu$ : $\sigma$ known, $n \geq 25$

- ▶ Two-sided  $1 - \alpha$  confidence interval:

$$\left( \bar{x} - z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{x} + z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}} \right)$$

- ▶ One-sided  $1 - \alpha$  **upper confidence interval**:

$$\left( -\infty, \bar{x} + z_{1-\alpha} \frac{\sigma}{\sqrt{n}} \right)$$

- ▶ One-sided  $1 - \alpha$  **lower confidence interval**:

$$\left( \bar{x} - z_{1-\alpha} \frac{\sigma}{\sqrt{n}}, \infty \right)$$

## Example: fill weight of jars

- ▶ Suppose a manufacturer fills jars of food using a stable filling process with a known standard deviation of  $\sigma = 1.6g$ .
- ▶ We take a sample of  $n=47$  jars and measure the sample mean weight  $\bar{x} = 138.2$  g.
- ▶ A two-sided 90% confidence interval ( $\alpha = 0.1$ ) for the true mean weight  $\mu$  is:

$$\begin{aligned} & \left( \bar{x} - z_{1-0.1/2} \frac{\sigma}{\sqrt{n}}, \bar{x} + z_{1-0.1/2} \frac{\sigma}{\sqrt{n}} \right) \\ &= \left( 138.2 - z_{0.95} \frac{1.6}{\sqrt{47}}, 138.2 + z_{0.95} \frac{1.6}{\sqrt{47}} \right) \\ &= (138.2 - 1.64 \cdot 0.23, 138.2 + 1.64 \cdot 0.23) \\ &= (137.82, 138.58) \end{aligned}$$

I could have also written the interval as:

$$138.2 \pm 0.38 \text{ g}$$

# Interpreting the confidence interval: fill weight of jars

- ▶ We are 90% confident that the true mean fill weight is between 137.82g and 138.58g.
- ▶ If we took 100 more samples of 47 jars each, roughly 90 of those samples would yield confidence intervals containing the true mean fill weight.
- ▶ These methods of interpretation generalize to all confidence intervals.

## Example: fill weight of jars.

- ▶ What if we just want to be sure that the true mean fill weight is high enough?
- ▶ Then, we would use a one-side lower 90% confidence interval:

$$\begin{aligned} & \left( \bar{x} - z_{1-\alpha} \frac{\sigma}{\sqrt{n}}, \infty \right) \\ &= \left( 138.2 - z_{1-\alpha} \frac{\sigma}{\sqrt{n}}, \infty \right) \\ &= \left( 138.2 - z_{0.9} \frac{1.6}{\sqrt{47}}, \infty \right) \\ &= (138.2 - 1.28 \cdot 0.23, \infty) \\ &= (137.91, \infty) \end{aligned}$$

- ▶ We're 90% confident that the true mean fill weight is above 137.91 g.

# Your turn: car engines

- ▶ Consider a grinding process used to rebuild car engines, which involves grinding rod journals for engine crankshafts.
- ▶ Of interest is the deviation of the true mean rod journal diameter from the target diameter.
- ▶ Suppose the standard deviation of the individual differences from the target diameter is  $0.7 \times 10^{-4}$  in.
- ▶ 32 consecutive rod journals are ground, with a sample mean deviation of  $-0.16 \times 10^{-4}$  in from the target diameter.
- ▶ Calculate and interpret a two-sided 95% confidence interval for the true mean deviation from the target diameter. Is there enough evidence that we're missing the target on average?

# Answer: car engines

- ▶  $\alpha = 1 - 0.95 = 0.05$ ,  $n = 32$ ,  $\sigma = 0.7 \times 10^{-4}$ , and  $\bar{x} = -0.16 \times 10^{-4}$ .

- ▶ Interval:

$$\begin{aligned} & \left( \bar{x} - z_{1-0.05/2} \frac{\sigma}{\sqrt{n}}, \bar{x} + z_{1-0.05/2} \frac{\sigma}{\sqrt{n}} \right) \\ &= \left( -0.16 \times 10^{-4} - z_{0.975} \frac{0.7 \times 10^{-4}}{\sqrt{32}}, -0.16 \times 10^{-4} + z_{0.975} \frac{0.7 \times 10^{-4}}{\sqrt{32}} \right) \\ &= \left( -0.16 \times 10^{-4} - 1.96 \cdot 1.2 \times 10^{-5}, -0.16 \times 10^{-4} + 1.96 \cdot 1.2 \times 10^{-5} \right) \\ &= \left( -4.0 \times 10^{-5}, 7.5 \times 10^{-6} \right) \end{aligned}$$

- ▶ We are 95% confident that the true mean deviation from the target diameter of the rod journals is between  $-4.0 \times 10^{-5}$  in and  $7.5 \times 10^{-6}$  in.
- ▶ Since 0 is in the confidence interval, there is not enough evidence to conclude that the rod journal grinding process is off target.

# Your turn: hard disk failures

- ▶ F. Willett, in the article The Case of the Derailed Disk Drives (Mechanical Engineering, 1988), discusses a study done to isolate the cause of blink code A failure in a model of Winchester hard disk drive.
- ▶ For each disk, the investigator measured the breakaway torque (in. oz.) required to loosen the drive's interrupter flag on the stepper motor shaft.
- ▶ Breakaway torques for 26 disk drives were recorded, with a sample mean of 11.5 in. oz.
- ▶ Suppose you know the true standard deviation of the breakaway torques is 5.1 in. oz.
- ▶ Calculate and interpret:
  1. A two-sided 90% confidence interval for the true mean breakaway torque of the relevant type of Winchester drive.
  2. An analogous two-sided 95% confidence interval.
  3. An analogous two-sided 99% confidence interval.
- ▶ Is there enough evidence to conclude that the mean breakaway torque is different from the factory's standard of 33.5 in. oz.?

# Answers: hard disk failures

- ▶  $\sigma = 5.1, \bar{x} = 11.5, n = 26$ .
- ▶ All three confidence intervals have the form:

$$\begin{aligned} & \left( \bar{x} - z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{x} + z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}} \right) \\ &= \left( 11.5 - z_{1-\alpha/2} \frac{5.1}{\sqrt{26}}, 11.5 + z_{1-\alpha/2} \frac{5.1}{\sqrt{26}} \right) \\ &= (11.5 - 1.0002 \cdot z_{1-\alpha/2}, 11.5 + 1.0002 \cdot z_{1-\alpha/2}) \end{aligned}$$

- ▶ The confidence intervals are thus:

1. 90% CI means  $\alpha = 0.1$

$$\begin{aligned} & (11.5 - 1.0002 \cdot z_{1-0.1/2}, 11.5 + 1.0002 \cdot z_{1-0.1/2}) \\ &= (11.5 - 1.0002 \cdot z_{0.95}, 11.5 + 1.0002 \cdot z_{0.95}) \\ &= (11.5 - 1.0002 \cdot 1.64, 11.5 + 1.0002 \cdot 1.64) \\ &= (9.86, 13.14) \end{aligned}$$

# Answers: hard disk failures

2. 95% CI means  $\alpha = 0.05$

$$\begin{aligned} & (11.5 - 1.0002 \cdot z_{1-0.05/2}, 11.5 + 1.0002 \cdot z_{1-0.05/2}) \\ &= (11.5 - 1.0002 \cdot z_{0.975}, 11.5 + 1.0002 \cdot z_{0.975}) \\ &= (11.5 - 1.0002 \cdot 1.96, 11.5 + 1.0002 \cdot 1.96) \\ &= (9.54, 13.46) \end{aligned}$$

3. 99% CI means  $\alpha = 0.01$

$$\begin{aligned} & (11.5 - 1.0002 \cdot z_{1-0.01/2}, 11.5 + 1.0002 \cdot z_{1-0.01/2}) \\ &= (11.5 - 1.0002 \cdot z_{0.995}, 11.5 + 1.0002 \cdot z_{0.995}) \\ &= (11.5 - 1.0002 \cdot 2.33, 11.5 + 1.0002 \cdot 2.33) \\ &= (9.17, 13.83) \end{aligned}$$

# Answers: hard disk failures

- ▶ Notice: the confidence intervals get wider as the confidence level  $1 - \alpha$  increases.
- ▶ None of these confidence intervals contains the manufacturer's target of 33.5 in. oz., so there is significant evidence that the process misses this target.
- ▶ Hence, there is a design flaw in the manufacturing process of the disk drives that must be corrected.

# Controlling the width of a confidence interval

- ▶ If you want to estimate the breakaway torque with a 2-sided, 95% confidence interval with  $\pm 2.0$  in. oz. of precision, what sample size would you need?
- ▶ The confidence interval is:

$$\begin{aligned} & \left( \bar{x} - z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{x} + z_{1-\alpha/2} \frac{\sigma}{\sqrt{n}} \right) \\ &= \left( 11.5 - z_{1-0.05/2} \cdot \frac{5.1}{\sqrt{n}}, 11.5 + z_{1-0.05/2} \cdot \frac{5.1}{\sqrt{n}} \right) \\ &= \left( 11.5 - z_{0.975} \cdot \frac{5.1}{\sqrt{n}}, 11.5 + z_{0.975} \cdot \frac{5.1}{\sqrt{n}} \right) \\ &= (11.5 - 1.96 \cdot 5.1 \cdot n^{-1/2}, 11.5 + 1.96 \cdot 5.1 \cdot n^{-1/2}) \\ &= (11.5 - 9.996 \cdot n^{-1/2}, 11.5 + 9.996 \cdot n^{-1/2}) \end{aligned}$$

# Controlling the width of a confidence interval

The interval precision (half-width)  $\delta$  is:

$$\begin{aligned}\delta &= \frac{1}{2} \left( (11.5 + 9.996 \cdot n^{-1/2}) - (11.5 - 9.996 \cdot n^{-1/2}) \right) \\ &= 9.996 \cdot n^{-1/2}\end{aligned}$$

We require  $\delta$  to be at most 2:

$$\begin{aligned}2.0 &\leq 9.996 \cdot n^{-1/2} \\ n &\geq 25\end{aligned}$$

- We would need a sample of 25 disk drives to meet a precision of  $\pm 2.0$ .
