Inference for Simple Linear Regression (Ch.

Will Landau

A Review of Simple Linear Regression (Ch. 4)

Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals
Inference for the
slope parameter

- The line, $y \approx 2.375+4.867 \times 10^{-5} x$, is the regression line fit to the data.

## Why fit a regression line?

1. To predict future values of $y$ based on $x$.

- I.e., a new ceramic under pressure $x=5000$ psi should have a density of $2.375+4.867 \times 10^{-5} \cdot 5000=2.618$ $\mathrm{g} / \mathrm{cc}$.

2. To characterize the relationship between $x$ and $y$ in terms of strength, direction, and shape.

- In the ceramics data, density has a strong, positive,

Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized residuals

Inference for the slope parameter linear association with $x$.

- On average, the density increases by $4.867 \times 10^{-5} \mathrm{~g} / \mathrm{cc}$ for every increase in pressure of 1 psi .

## Fitting a linear regression line

- For a response variable $y$ and a predictor variable $x$, we declare:

$$
y \approx b_{0}+b_{1} x
$$

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals
Inference for the slope parameter

- and then calculate the intercept $b_{0}$ and slope $b_{1}$ using least squares.
- We apply the principle of least squares: that is, the best-fit line is given by minimizing the loss function in terms of $b_{0}$ and $b_{1}$ :

$$
S\left(b_{0}, b_{1}\right)=\sum_{i=1}^{n}\left(y_{i}-\widehat{y}_{i}\right)^{2}
$$

- Here, $\widehat{y}_{i}=b_{0}+b_{1} x_{i}$

Minimize $\sum_{i=1}^{n}\left(y_{i}-\hat{y}_{i}\right)^{2}$ to get the line as close as possible to the points.

## Will Landau

- From the principle of least squares, one can derive the normal equations:

$$
\begin{aligned}
n b_{0}+b_{1} \sum_{i=1}^{n} x_{i} & =\sum_{i=1}^{n} y_{i} \\
b_{0} \sum_{i=1}^{n} x_{i}+b_{1} \sum_{i=1}^{n} x_{i}^{2} & =\sum_{i=1}^{n} x_{i} y_{i}
\end{aligned}
$$

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals
Inference for the slope parameter

- and then solve for $b_{0}$ and $b_{1}$ :

$$
b_{1}=\frac{\sum\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{\sum\left(x_{i}-\bar{x}\right)^{2}} \quad b_{0}=\bar{y}-b_{1} \bar{x}
$$

## Example: plastics hardness data

Eight batches of plastic are made. From each batch one test item is molded. At a given time (in hours), it hardness is measured in units (assume freshly-melted plastic has a hardness of 0 units). The following are the 8 measurements and times.

Estimating $\sigma^{2}$
Standardized
residuals
Inference for the
slope parameter

## Interpret the model terms

- $b_{1}=2.43$ means that on average, the plastic hardens 2.43 more units for every additional hour it is allowed to harden.

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals
Inference for the slope parameter

- But we know that the plastics were completely molten at the very beginning, with a hardness of 0 .
- Don't extrapolate: i.e., predict $y$ values beyond the range of the $x$ data.

## Linear correlation: a measure of usefulness

- Linear correlation: a measure of usefulness of a fitted

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals

- As it turns out:

$$
r=b_{1} \frac{s_{x}}{s_{y}}
$$

where $s_{x}$ is the standard deviation of the $x_{i}$ 's and $x_{y}$ is the standard deviation of the $y_{i}$ 's.

## Facts about linear correlation

Inference for Simple Linear Regression (Ch. 9.1)

## Will Landau

- $-1 \leq r \leq 1$
- $r<0$ means a negative slope, $r>0$ means a positive slope
- High $|r|$ means $x$ and $y$ have a strong linear relationship (high correlation), and low $|r|$ implies a weak linear relationship (low correlation).

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals

Inference for the slope parameter

## Coefficient of determination

 usefulness of a fitted line, defined by:$$
R^{2}=\frac{\sum\left(y_{i}-\bar{y}\right)^{2}-\sum\left(y_{i}-\widehat{y}_{i}\right)^{2}}{\sum\left(y_{i}-\bar{y}\right)^{2}}
$$

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals
Inference for the slope parameter

- Interpretation: $R^{2}$ is the fraction of variation in the response variable ( $y$ ) explained by the fitted line.
- Ceramics data: $R^{2}=r^{2}=0.9911^{2}=0.9823$, so $98.2279 \%$ of the variation in density is explained by pressure. Hence, the line is useful for predicting density from pressure.
- Plastics data: $R^{2}=r^{2}=0.9796^{2}=0.9596$, so $95.9616 \%$ of the variation in hardness is explained by time. Hence, so the line is useful for predicting hardness from time.

Estimating $\sigma^{2}$
Standardized
residuals
Inference for the slope parameter

## Standardized residuals

Inference for the slope parameter

## The informal simple linear regression model

- Up until now, we have looked at fitted lines of the form:

$$
y_{i}=b_{0}+b_{1} x_{i}+e_{i}
$$

where:

- $y_{1}, y_{2}, \ldots, y_{n}$ are the fixed, observed values of the response variable.
- $x_{1}, x_{2}, \ldots, x_{n}$ are the fixed, observed values of the predictor variable.

A Review of
Simple Linear

Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals
Inference for the slope parameter

- $b_{0}$ is the estimated slope of the line based on sample data.
- $b_{1}$ is the estimated intercept of the line based on sample data.
- $e_{i}$ is the residual of the $i$ 'th unit of the sample.

## The formal simple linear regression model

$$
Y_{i}=\beta_{0}+\beta_{1} x_{i}+\varepsilon_{i}
$$

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals
Inference for the slope parameter

- $\beta_{0}$ is a parameter denoting the true intercept of the line if we fit it to the population.
- $\beta_{1}$ is a parameter denoting the true slope of the line if we fit it to the population.
- $\varepsilon_{1}, \varepsilon_{2}, \ldots, \varepsilon_{n}$ are random variables called error terms.

## The formal simple linear regression model

Inference for Simple Linear Regression (Ch.

- We assume:

$$
\varepsilon_{1}, \varepsilon_{2}, \ldots, \varepsilon_{n} \stackrel{\text { iid }}{\sim} N\left(0, \sigma^{2}\right)
$$

- Which means that for all $i$ :

$$
Y_{i} \stackrel{\mathrm{iid}}{\sim} N\left(\beta_{0}+\beta_{1} x_{i}, \sigma^{2}\right)
$$

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals
Inference for the slope parameter

- We often say:

$$
\mu_{y \mid x}=\beta_{0}+\beta_{1} x
$$

## The formal simple linear regression model

Inference for Simple Linear Regression (Ch.

$x$

## Standardized residuals

Inference for the slope parameter

## The line-fitting sample variance

Inference for Simple Linear Regression (Ch.
9.1)

Will Landau

- $\hat{y}_{i}=b_{0}+b_{1} x_{i}$
- $e_{i}=y_{i}-\widehat{y}_{i}$
- The line-fitting sample variance, also called mean squared error (MSE) is:

$$
s_{L F}^{2}=\frac{1}{n-2} \sum_{i}\left(y_{i}-\widehat{y}_{i}\right)^{2}=\frac{1}{n-2} \sum_{i} e_{i}^{2}
$$ and it satisfies:

$$
E\left(s_{L F}^{2}\right)=\sigma^{2}
$$

- The line-fitting sample standard deviation is just $s_{L F}=\sqrt{s_{L F}^{2}}$

## Example: ceramics

- A mixture of $\mathrm{Al}_{2} \mathrm{O}_{3}$, polyvinyl alcohol, and water was prepared, dried overnight, crushed, and sieved to obtain 100 mesh size grains. These were pressed into cylinders at pressures from 2,000 psi to 10,000 psi, and cylinder densities were calculated.

| $x$, <br> Pressure (psi) | $y$, <br> Density (g/cc) |
| :---: | :---: |
| 2,000 | 2.486 |
| 2,000 | 2.479 |
| 2,000 | 2.472 |

## Example: ceramics

Inference for Simple Linear Regression (Ch.

Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized
residuals
Inference for the
slope parameter

## Example: ceramics

- The fitted least squares line is $\widehat{y}_{i}=2.375+0.0000487 x_{i}$.
- The fitted values $\widehat{y}_{i}$ are:

Inference for Simple Linear Regression (Ch.
9.1)

Will Landau
Fitted Density Values

| $x$, Pressure | $\hat{y}$, Fitted Density |
| :---: | :---: |
| 2,000 | 2.4723 |
| 4,000 | 2.5697 |
| 6,000 | 2.6670 |
| 8,000 | 2.7643 |
| 10,000 | 2.8617 |

A Review of
Simple Linear
Regression (Ch.
Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$
Standardized residuals

- And $\sum\left(y_{i}-\widehat{y}_{i}\right)^{2}$ is:

Inference for the slope parameter

$$
\begin{aligned}
\sum\left(y_{i}-\hat{y}_{i}\right)^{2}= & (2.486-2.4723)^{2}+(2.479-2.4723)^{2}+(2.472-2.4723)^{2} \\
& +(2.558-2.5697)^{2}+\cdots+(2.879-2.8617)^{2} \\
& +(2.858-2.8617)^{2} \\
= & .005153
\end{aligned}
$$

- Thus, $s_{L F}^{2}=\frac{1}{n-2} \sum\left(y_{i}-\widehat{y}_{i}\right)^{2}=\frac{1}{15-2} \cdot 0.005153=0.00396(g / c c)^{2}$
$-s_{L F}=\sqrt{s_{L F}^{2}}=0.0199 g / c c$

residuals

- Thus:

$$
Z=\frac{b_{1}-\beta_{1}}{\frac{\sigma}{\sqrt{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}}}} \sim N(0,1)
$$

and

$$
T=\frac{b_{1}-\beta_{1}}{\frac{s_{L F}}{\sqrt{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}}}} \sim t_{n-2}
$$

## Inference for the slope parameter

Inference for Simple Linear
Regression (Ch.
9.1)

Will Landau

- If we want to test $H_{0}: \beta_{1}=\#$, we can use the test statistic:

$$
K=\frac{b_{1}-\#}{\frac{s_{L F}}{\sqrt{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}}}} \sim t_{n-2}
$$

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model
which has a $t_{n-2}$ distribution if $H_{0}$ is true and the model assumptions are true.

- We can write a two-sided $1-\alpha$ confidence interval as:

Estimating $\sigma^{2}$
Standardized
residuals
Inference for the slope parameter

- The one-sided confidence intervals are analogous.

## Example: ceramics

- I will construct a two-sided $95 \%$ confidence interval for $\beta_{1}$ ( $\alpha=0.05$ ).
- From before, $b_{1}=0.0000487 \mathrm{~g} / \mathrm{cc} / \mathrm{psi}$, $\sum_{i}\left(x_{i}-\bar{x}\right)^{2}=1.2 \times 10^{8}$, and $s_{L F}=0.0199$.
- $t_{n-2,1-\alpha / 2}=t_{13,0.975}=2.16$.
- The confidence interval is then:

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model
Estimating $\sigma^{2}$

Inference for Simple Linear Regression (Ch 9.1)

## Will Landau

1. $H_{0}: \beta_{1}=0, H_{a}: \beta_{1} \neq 0$.
2. $\alpha=0.05$
3. Use the test statistic:

$$
K=\frac{b_{1}-0}{\frac{S_{L F}}{\sqrt{\sum\left(x_{i}-\bar{x}\right)^{2}}}}=\frac{b_{1}}{\widehat{S D}\left(b_{1}\right)}
$$

I assume:

- $\mathrm{H}_{0}$ is true.
- The model, $Y_{i}=\beta_{0}+\beta_{1} x_{i}+\varepsilon_{i}$ with errors $\varepsilon_{i} \sim$ iid $N\left(0, \sigma^{2}\right)$, is correct.
Under these assumptions, $K \sim t_{n-2}=t_{15-2}=t_{13}$

## Answers: ceramics

4. The moment of truth:

A Review of
Simple Linear
Regression (Ch. 4)
Formalizing the
Simple Linear
Regression Model

$$
\text { p-value }=P\left(\left|t_{13}\right|>|26.8|\right)=P\left(t_{13}>26.8\right)+P\left(t_{13}<-26.8\right)
$$

Estimating $\sigma^{2}$

$$
<0.0001 \quad \text { ("Prob }>|t| " \text { in JMP output) }
$$

Standardized residuals

Inference for the slope parameter
5. With a p-value $<0.0001<0.05=\alpha$, we reject $H_{0}$ and conclude $\mathrm{H}_{\mathrm{a}}$.
6. There is overwhelming evidence that the true slope of the line is different from 0 .
